## SUMMARY

Seven three-inch diameter core samples from the Pennsylvanian Marmaton and Cherokee Groups were collected from the Layne-Christensen #16-1 Pierce well, NE SE SW 16-T.31S.-R.17E., Montgomery County, KS from May 28 to May 31, 2003. The following as-received gas contents were measured, based on the dry weight of the sample:

- 471.0' to 471.8' (Lexington "B" coal) (139.5 scf/ton)
- 569.0' to 570.0' (Excello Shale) ( 40.0 scf/ton)
- 571.1' to 572.0' (Mulky coal) (188.1 scf/ton)
- 875.5' to 876.4' (Dry Wood coal) (189.9 scf/ton)
- 910.7' to 911.4' (Neutral(?) coal) (110.7 scf/ton)
- 982.0' to 983.0' (Riverton coal) (144.2 scf/ton)
- 983.0' to 984.0' (Riverton coal) ( 74.1 scf/ton)

Analyses of five desorbed coal gases indicate that they are dry gases, ranging from 952 to 1041 BTU/scf. Nitrogen and carbon dioxide are the major non-combustible component gases. Carbon dioxide contents range from 1.4% to 3.6%. Isotopic analysis indicate the gas is mixed thermogenic and biogenic in origin.

Based on gas content, density, and thickness measurements, the gas-in-place estimates for the respective units are:

<i>unit</i>	<i>gas per acre (thousand cubic ft)</i>
Lexington "B"	345.2
Excello Sh.	399.4
Mulky	347.8
Dry Wood	289.2
Neutral(?)	111.4
Riverton	467.7

## BACKGROUND

The Layne-Christensen #16-1 Pierce well; NE SE SW 16-T.31S.-R.17E., Montgomery County, KS, was selected for desorption tests in association with an on-going coalbed-gas research project at the Kansas Geological Survey. The samples (3-inch-diameter cores) were gathered from May 28, 2003 to May 31, 2003 by K. David Newell of the Kansas Geological Survey, with assistance by Jim Stegeman of Colt Energy. Samples were obtained by wireline coring on a rig owned by Layne-Christensen, Canada.

Bottom-hole times (i.e., the time the core sample was lifted from the bottom of the hole) and canistering times (i.e., the time the sample was placed in the desorption canister) were noted in order to determine lost gas and start of desorption. Approximate wet weight of the sample was determined by subtraction of the weight of the empty canister from the weight of the canister with the sample in it. After the sample was removed from the canister, it was weighed again

before air-drying, then weighed after drying. The weight loss is noted in the desorption table (Table 1).

Temperature baths for the desorption canisters were on site, with temperatures at 75 °F for the Mulky coal and shallower samples. Samples deeper than the Mulky coal were desorbed at 80 °F. The canistered samples were transported to the laboratory at the Kansas Geological Survey in Lawrence, KS after their collection at the wellsite and desorption measurements were continued at these temperatures. Desorption measurements were periodically made until the canisters produced no more gas upon testing for at least two successive measurements.

## DESORPTION MEASUREMENTS

The equipment and method for measuring desorption gas is that prescribed by McLennan and others (1995). The volumetric displacement apparatus is a set of connected dispensing burettes, one of which measures the gas evolved from the desorption canister. The other burette compensates for the compression that occurs when the desorbed gas displaces the water in the measuring burette. This compensation is performed by adjusting the cylinders so that their water levels are identical, then figuring the amount of gas that evolved by reading the difference in water level using the volumetric scale on the side of the burette.

Some of the canisters utilized for this study (i.e., canisters with the prefix "Mer") were obtained from PEL-I-CANS (by J.R. Levine) in Richardson, TX. These canisters are approximately 11.2 inches high (28.5 cm), 3.8 inches (9.7 cm) in diameter, and enclose a volume of approximately 127 cubic inches (2082 cm<sup>3</sup>). The rest of the canisters utilized for this study were obtained from SSD, Inc. in Grand Junction, CO. On average, these canisters are approximately 12.5 inches high (32 cm), 3 1/2 inches (9 cm) in diameter, and enclose a volume of approximately 150 cubic inches (2450 cm<sup>3</sup>). The desorbed gas that collected in the desorption canisters was periodically released into the volumetric displacement apparatus and measured as a function of time, temperature, and atmospheric pressure.

The time and atmospheric pressure were measured in the field using a portable weather station (model BA928) marketed by Oregon Scientific (Tualatin, OR). The atmospheric pressure was displayed in millibars on this instrument, however, this measurement was not the actual barometric pressure, but rather an altitude-compensated barometric pressure automatically converted to a sea-level-equivalent pressure. To translate this measurement to actual atmospheric pressure, a regression correlation was determined over several weeks by comparing readings from the Oregon Scientific instrument to that from a pressure transducer in the Petrophysics Laboratory in the Kansas Geological Survey (Figure 1). The regression equation shown graphically in Figure 1 was entered into a spreadsheet and was used to automatically convert the millibar measurement to barometric pressure in psi.

A spreadsheet program written by K.D. Newell was used to convert all gas volumes at standard temperature and pressure. Conversion of gas volumes to standard temperature and pressure was by application of the perfect-gas equation, obtainable from basic college chemistry texts:

$$n = PV/RT$$

where n is moles of gas, T is degrees Kelvin (i.e., absolute temperature), V is in liters, and R is the universal gas constant, which has a numerical value depending on the units in which it is measured (for example, in the metric system  $R = 0.0820$  liter atmosphere per degree mole). The number of moles of gas (i.e., the value n) is constant in a volumetric conversion, therefore the conversion equation, derived from the ideal gas equation, is:

$$(P_{\text{stp}}V_{\text{stp}})/(RT_{\text{stp}}) = (P_{\text{rig}}V_{\text{rig}})/(RT_{\text{rig}})$$

Customarily, standard temperature and pressure for gas volumetric measurements in the oil industry are 60 °F and 14.7 psi (see Dake, 1978, p. 13), therefore  $P_{\text{stp}}$ ,  $V_{\text{stp}}$ , and  $T_{\text{stp}}$ , respectively, are pressure, volume, and temperature at standard temperature and pressure, where standard temperature is degrees Rankine ( $^{\circ}\text{R} = 460 + ^{\circ}\text{F}$ ).  $P_{\text{rig}}$ ,  $V_{\text{rig}}$ , and  $T_{\text{rig}}$ , respectively, are ambient pressure, volume, and temperature measurements taken at the rig site or in the desorption laboratory.

The universal gas constant R drops out as this equation is simplified and the determination of  $V_{\text{stp}}$  becomes:

$$V_{\text{stp}} = (T_{\text{stp}}/T_{\text{rig}}) (P_{\text{rig}}/P_{\text{stp}}) V_{\text{rig}}$$

The conversion calculations in the spreadsheet were carried out in the English metric system, as this is the customary measure system used in American coal and oil industry. V is therefore converted to cubic feet; P is psia; T is °R.

The desorbed gas was summed over the time period for which the coal samples evolved all of their gas.

Lost gas (i.e., the gas lost from the sample from the time it was drilled, brought to the surface, to the time it was canistered) was determined using the direct method (Kissel and others, 1975; also see McLennan and others, 1995, p. 6.1-6.14) in which the cumulative gas evolved is plotted against the square root of elapsed time. Time zero is assumed to be instant the core sample is lifted from the bottom of the hole. Characteristically, the cumulative gas evolved from the sample, when plotted against the square root of time, is linear for a short time period after the sample reaches ambient pressure conditions, therefore lost gas is determined by a line projected back to time zero. The period of linearity generally is about two hours for core samples.

## LITHOLOGIC ANALYSIS

Upon removal from the canisters, the cores were washed of drilling mud, and air-dried for several days. After drying, the cores were weighed again to obtain a dry-weight based gas content.

## DATA PRESENTATION

Data and analyses accompanying this report are presented in the following order: 1) data tables for the desorption analyses, 2) lost-gas graphs, 3) desorption graphs for individual samples, and 4) desorption graph for all samples at a common scale, 5) gas chemistry diagrams, and 6) reserve diagrams.

### *Data Tables of the Desorption Analyses (Table 1)*

These are the basic data used for lost-gas analysis and determination of total gas desorbed from the core samples. Basic temperature, volume, and barometric measurements are listed at left. Farther to the right, these are converted to standard temperature, pressure and volumes. The volumes are cumulatively summed, and converted to scf/ton based on the total weight of coal and dark shale in the sample. At the right of the table, the time of the measurements are listed and converted to hours (and square root of hours) since the sample was drilled.

### *Lost-Gas Graphs (Figures 2-8)*

Gas lost prior to the canistering of the sample was estimated by extrapolation of the first few data points after the sample was canistered. The linear characteristic of the initial desorption measurements was usually lost within the first two hours after canistering, thus data are presented in the lost-gas graphs for only up to 9 hours after canistering. Lost-gas volumes derived from this analysis are incorporated in the data tables described above.

### *Desorption Graphs (Figures 9-16)*

Desorption graphs for individual samples are presented in Figures 8-14. A summary graph showing all the samples at a common scale is presented in Figure 15. A second summary graph (Figure 16) expresses the desorption in terms of percentage of the total gas desorbed with time. Sorption times (the time it takes for 63.2% of the gas from a sample to desorb) are derived from this latter figure.

### *Gas Chemistry (Figure 17-18)*

Gas isotopic chemistry is compared to similar analyses on other nearby coalbed gases, with respect to the local stratigraphy (Figure 17). The crossplot of chemistry and location of samples is shown in Figure 18.

### *Reserve Estimate (Figure 19)*

Gas reserves are calculated based on desorption data, and crossplotted with sorption time, which is a semi-quantitative indicator of production rates.

### *Appendix 1*

These are photocopies of the results of the Luman's Laboratories proximate analyses.

## RESULTS and DISCUSSION

The following as-received gas contents are calculated, based on dry weight of the sample:

- 471.0' to 471.8' (Lexington "B" coal) (139.5 scf/ton)
- 569.0' to 570.0' (Excello Shale) ( 40.0 scf/ton)
- 571.1' to 572.0' (Mulky coal) (188.1 scf/ton)
- 875.5' to 876.4' (Dry Wood coal) (189.9 scf/ton)
- 910.7' to 911.4' (Neutral(?) coal) (110.7 scf/ton)
- 982.0' to 983.0' (Riverton coal) (144.2 scf/ton)
- 983.0' to 984.0' (Riverton coal) ( 74.1 scf/ton)

Proximate analyses were made for ten selected samples . The core was cut down its vertical axis and half was preserved for future analyses. The proximate analyses were performed on the following samples by Luman's Laboratory (see Appendix 1):

Luman's Lab proximate analysis:

<i>unit</i>	<i>depth</i>	<i>moisture</i>	<i>ash</i>	<i>moisture-free ash</i>
Lexington "B"	471.0'	1.42%	18.82%	19.10%
Excello Sh.	569.0'	0.97%	72.10%	72.81%
Mulky	571.1'	1.25%	15.95%	16.16%
Dry Wood	875.5'	2.69%	25.21%	25.90%
Neutral(?)	910.7'	2.61%	30.31%	31.13%
Riverton	982.0'	1.41%	8.86%	8.99%
Riverton	983.0'	1.84%	41.64%	42.42%

According to the BTU/lb. (dry, ash-free) determinations, all the samples can be classified as high-volatile A bituminous coal. The dry, ash-free heating value of the Excello Shale sample, at 19,632 BTU/lb., is enigmatic. Nevertheless, a rather inflated calculation for this particular unit appears to be a consistent characteristic, for a nearby well (the Layne-Christensen #1 Beurskens well in sec. 28-T.31S.-R.16E.; also in Montgomery County), also yielded a high value for this measurement. These are the first two ashing measurements of the Excello Shale that have been brought to the attention of the Kansas Geological Survey, so the spatial extent of this behavior or its cause is not yet known. A possible explanation is that the Excello may contain considerable amount of oil, which may serve to increase its apparent heat content.

Using the equation from McLennan and others (1995):

$$G_c = G_{pc} (1-a_d)$$

where:

$G_c$  = gas content, scf/ton

$G_{pc}$  = "pure coal", gas content, scf/ton

$a_d$  = dry ash content, weight fraction

the gas content of the samples converts to:

<i>unit</i>	<i>depth</i>	<i>moisture-free ash</i>	<i>Gc</i>	<i>Gpc</i>
Lexington "B"	471.0'	19.10%	139.5 scf/ton	172.4 scf/ton
Excello Sh.	569.0'	72.81%	40.0 scf/ton	147.3 scf/ton
Mulky	571.1'	16.16%	188.1 scf/ton	224.4 scf/ton
Dry Wood	875.5'	25.90%	189.9 scf/ton	256.3 scf/ton
Neutral(?)	910.7'	31.13%	110.7 scf/ton	160.7 scf/ton
Riverton	982.0'	8.99%	144.2 scf/ton	158.4 scf/ton
Riverton	983.0'	42.42%	74.1 scf/ton	128.7 scf/ton

Samples were also tested for their density. Dried samples were weighed and immersed in water in a beaker filled to its brim. With placing the sample in the beaker, the displaced water was spilled from the beaker and subsequently weighed. The volume of the sample is thus easily converted to volume using 1 gram/cc for the density of the water. The following density measurements were calculated:

<i>unit</i>	<i>depth</i>	<i>density and uncertainty</i>
Lexington "B"	471.0'	1.40 g/cc $\pm$ 0.04
Excello Shale	569.0'	2.16 g/cc $\pm$ 0.09
Mulky	571.1'	1.36 g/cc $\pm$ 0.01
Dry Wood	875.5'	1.40 g/cc $\pm$ 0.03
Neutral(?)	910.7'	1.48 g/cc $\pm$ 0.02
Riverton	982.0'	1.28 g/cc $\pm$ 0.07
Riverton	983.0'	1.71 g/cc $\pm$ 0.19

Compositional and isotopic chemistry were performed on five gas samples. These analyses are in Appendix II and were performed by Isotech Laboratories in Champaign, IL.

#### Summary

	L'ton	Excello	Mulky	Dry Wood	Riverton
Calculated BTU	952	1026	1020	1019	1041
Total % non-HCs	10.51	2.95	3.64	3.71	3.46
HC Wetness (%)	0.77	0.07	0.10	0.16	1.25

Plotting of the isotopes and gas wetness (Figure 18) indicates that the gas is of mixed biogenic and thermogenic origin.

An estimate of gas reserves per acre for the coals and shales tested can be made using thickness, density, and gas content data:

unit	thickness <sup>1</sup> (ft)	coal/shale per acre (ft <sup>3</sup> ) <sup>2</sup>	(ton) <sup>3</sup>	gas per acre (thousand cubic ft) <sup>4</sup>
Lexington "B"	1.3	56,628	2,475	345.2
Excello Sh.	3.4	148,104	9,986	399.4
Mulky	1.0	43,560	1,849	347.8
Dry Wood	0.8	34,848	1,523	289.1

Neutral(?)	0.5	21,780	1,006	111.4
Riverton	2.1	91,476	4,283 <sup>5</sup>	467.7 <sup>5</sup>

<sup>1</sup>thicknesses (ft) from Rolland Yoakum, Layne Energy (personal communication, 2005)

<sup>2</sup>thickness (ft) X 43,560 ft<sup>2</sup>/acre

<sup>3</sup>ft<sup>3</sup> coal or shale per acre X density (g/cm<sup>3</sup>) X (1/ 907,168 g/ton) X 28,317 cm<sup>3</sup>/ft<sup>3</sup>

<sup>4</sup>tons coal or shale per acre X gas content (ft<sup>3</sup>/ton)

<sup>5</sup>averaged density (1.50 g/cm<sup>3</sup>) and gas content (109.2 ft<sup>3</sup>/ton) used

Sorption times (time required to desorb 63.2% of the total gas content) for the samples are as follows (see Figure 26):

<i>unit</i>	<i>depth</i>	<i>sorption time (days)</i>
Lexington "B"	677.8'	182.6
Excello Shale	681.5'	17.7
Mulky	682.4'	12.8
Dry Wood	706.0'	63.5
Neutral(?)	731.5'	16.3
Mineral	772.0'	36.7
Riverton	1053.7'	13.0
Riverton	1054.7'	10.6
Lexington "B"	471.0'	34.9
Excello Shale	569.0'	85.7
Mulky	571.1'	31.0
Dry Wood	875.5'	10.2
Neutral(?)	910.7'	11.5
Riverton	982.0'	22.1
Riverton	983.0'	20.0

A reserves versus sorption time diagram is shown in Figure 19.
